- A composition used as a therapeutic agent against chronic viral hepatic diseases.
- (g) A combination, comprising at least one polypeptide sequence, mediating the antigenicity of one or more epitopes, and a carrier, capable of presenting this/these polypeptide sequence(s), which are useful for the production of a medicament for the treatment of chronic viral hepatitis, is provided.

The present invention relates to a composition comprising a polypeptide sequence prepared by recombinant DNA techniques and a carrier to provide a curing agent against chronic viral hepatic diseases. The invention relates to DNA sequences coding for said polypeptide sequences and to transfected cells for the expression of the same.

At least five different viruses, namely Hepatitis virus A, B, C, D and E, are able to trigger the clinical aspect of an acute hepatitis. Hepatitis A and E, which are transferred enterically, always heal, whereas hepatitis B, C (formerly called parenteral hepatitis Non-A Non-B), and D can progress into a chronic stage of inflammation, which in turn can result in liver cirrhosis and primary hepatocellular carcinoma.

There is relatively little data available on hepatitis C and D, on methods for the diagnosis and their treatment and on the respective viruses. The hepatitis D virus is a RNA virus which is known to be incomplete. Therefore, it needs a helper virus to develop in patients and is found only in individuals infected with HBV. Only very recently the hepatitis C virus has been detected, and an antibody test (anti-HCV) facilitating the diagnosis of chronic hepatitis C infections has been developed. However, there is an increasingly urgent need for a treatment to cure this disease.

The same holds true for chronic hepatitis B, a much better studied disease with respect to its recognition by immunological methods, its causative virus and the viral life cycle and DNA sequence. Patients are said to be chronic carriers of the hepatitis B virus if the viral DNA persists longer than ten weeks, the HBe-antigen (HBeAg) for more than 12 weeks, or if the hepatitis B surface-antigen (HBsAg) is persistent longer than six months.

Roughly three hundred million people are deemed to suffer from chronic hepatitis B, most of them living in the Far East.

20

40

For these people the main risk to be infected appears to be during or immediately after birth, since a chronically infected mother transfers the virus to her newborn. 90 percent of the children infected this way will become chronically infected, too, during later life. In the Western World infection occurs more commonly later in life, during childhood or even adulthood, mainly by a parenteral or sexual transmission. In these cases of hepatitis B infection after birth only five to ten percent of the infected become chronic carriers. The virus transferred, however, is not responsible for distinct reactions shown by infected people either to eliminate the virus or to retain it in the body lifelong. Consequently, it seems to be a matter of the immunological status that determines the future physical condition.

The HB-virion (Dane particle) is composed of different structural proteins, the core proteins and the surface (S) proteins. The latter are translation products of an open reading frame encompassing the coding sequence of three S-type domains, each of which starts with an ATG triplet capable of initiating translation in vivo. The domains are referred to as preS1, preS2 and S in the order of 5' to the 3'end of the molecule. There are six protein products derived from this ORF: a glycosylated and a non-glycosylated form of the major protein (gp27 and p24) translated from the S domain only (226 amino acids), a middle protein (281 amino acids) having one or two polysaccharide side chains (gp33 and gp36, respectively), that is encoded by the preS2- and S-region, and finally, both a glycosylated (gp42) and a non-glycosylated (p39) form of the large protein (389-400 amino acids, depending upon the viral serotype), which is formed by translation of preS1, preS2 and S. The core proteins are HBcAg and HBeAg, the latter one conceivably being a processing product of HBcAg.

The Dane particle, which is the infectious virion, comprises both core and surface proteins, whereas the filaments consist of a mixture of the six surface antigens. The S peptides alone assemble to form the so-called 20nm particles, which are completely uninfectious.

Patients infected by the HB virus pass through several stages of the hepatitis, before they are regarded to be chronically HBV-infected. Immediately after infection an infectious stage will follow, characterized by the presence of HBeAg in the serum. Continued HBs antigenaemia in spite of inhibited HBV replication indicates the presence of viral DNA sequences integrated into the cellular genome of the patient. The integrated viral sequences do not enable the host cell to synthesize the complete virus. However, liver cells having HBV-sequences integrated are capable of producing HBsAg only, which in turn is detectable in the serum of the patient and is an indicator for chronic hepatitis B. Most probably the transformed hepatocytes are not lysed by cytotoxic T-cells, but proliferate and induce either chronic persistent hepatitis (CPH) or chronic active hepatitis (CAH), which may then proceed to cirrhosis of the liver or to primary hepatocellular carcinoma resulting in premature death of the patient.

Recently it has been established that patients who are chronically HBV infected show a defect in endogenous interferon production (Abb et al., 1985: J. Med. Virol 16, 171-176). This was the rationale to treat patients suffering from chronical hepatitis B, as indicated by the presence of HBeAg and HBV-DNA in the serum, with interferon α (IFN α). Controlled trials with large numbers of patients showed that the administration of interferon α resulted in significantly increased elimination of the hepatitis B-virus, when

compared to controls. However, persons infected at or around time of birth do not appear to seroconvert in response to this therapy. This phenomenon unfortunately precludes some 75% of carriers from IFN α therapy.

At present, the exact mode of action of interferon α on chronic hepatitis B remains unclear. Its antiviral activity might protect infected cells from infection or reduce viral transcription, translation and replication in HBV-infected cells. Interferon further has immunomodulatory effects by activating T-cells, macrophages and NK-cells and by inducing the expression of MHC class I proteins.

Another approach to treat chronic hepatitis B is based on the idea to inhibit replication of the virus, thus impairing its defence sufficiently to render the host immune system capable of eliminating the virus. This led to test antiviral drugs such as adenine arabinoside and adenine arabinoside monophosphate for treatment of chronically HBV infected individuals. However, less than half of the patients responded to this therapy, either by sustained or transient seroconversion (HBeAg to anti-HBe). A further negative aspect of these antiviral drugs are their immunosuppressive properties. Other drugs that have been tested for treatment of chronic carriers include interferon β and acycloguanosine (acyclovir), interleukin 2, steroids, such as prednisolone, and combinations thereof. But none of them could provide better results than treatment with interferon α . Only a combination therapy, including the initial administration of steroids followed by that of IFN α may increase the response rate in selected patients.

It is known from the prior art, that chronically HBV infected chimpanzees can not be cured by treatment with HBsAg (bound to a tetanus toxoid) nor with anti-HBs antibodies. Furthermore, it has been attempted to immunize chronically HBV infected patients by administration of S peptides. This treatment did not even result in anti-HBs antibody formation in these persons.

Additionally, according to the definition, chronic carriers of hepatitis B virus are characterized in that HBsAg is detectable in their serum. Therefore, it has been absolutely unforeseeable, that a combination, comprising a T-cell activating epitope of the viral S peptide, according to the present invention, is able to induce an immunization in and a final healing of chronic carriers of hepatitis virus B.

Considering the above-discussed state of the art it is the objective of the present invention to provide an effective therapeutic agent for the treatment of viral chronic hepatic diseases which leads to a complete response (i.e. to the sustained inhibition of HBV-replication, the loss of HBV DNA and DNA polymerase and to a decrease and finally the disappearance of HBeAg and HBsAg in the serum of patients).

According to the present invention this goal is achieved by a combination of a) at least one polypeptide sequence mediating the antigenicity of one or more epitopes and b) a carrier, capable of presenting the epitope sequence(s) a), wherein the polypeptide sequence(s) a) can be bound to carrier b) by adsorption, any chemical bonding or secondary valences.

This invention is furthermore directed to the use of this combination for the production of a medicament for the treatment of chronic viral hepatitis.

It is important that polypeptide sequence a), which may be one or more different polypeptides, mediates the antigenicity of a T cell-activating epitope in a direct or indirect way. According to the present invention polypeptide sequence(s) a) may be a polypeptide or a combination of two or more polypeptides of hepatitis B virus of any subtype, particularly adw, ayw, adr and ady.

These peptides derived from hepatitis B virus may be HBV peptides preS1, preS2 or S or the HBV core antigens.

Useful as polypeptide sequence(s) a) are futhermore any of the above-stated polypeptides or a combination of two or more polypeptides which are modified either by amino acid deletions, whereby at least one epitope comprising at least six consecutive amino acid residues must be preserved, or by adding further amino acids either at the N-terminus, the C-terminus or as insertions into the polypeptide sequence-(s) a). In each of these cases it is essential, however, that the biologial activity is maintained.

Preferably, polypeptide sequence(s) a) is myristylated.

30

In order to display the appropriate pharmacological activity it is necessary that in the combination of the present invention polypeptide sequence(s) a) is presented on a carrier b). This carrier consists of a particular substance which for example may consist of particles of a hydrophobic polymer, of inorganic particles, or of particles of a polysaccharide. Preferably, carrier b) is a second polypeptide sequence which forms particles upon secretion, said particles having preferably a diameter of at least 10nm.

It is preferred that the particle forming polypeptide sequence b) is a substantial part of or the complete amino acid sequence of a polypeptide which may be selected from HBV S peptide, HBV core antigen, HAV core antigen, HAV surface antigen, HIV surface antigen and HIV core antigen as well as the surface antigen of polio virus. Preferred as the particle-forming carrier b) is HBV S peptide and/or core peptide.

When used as the carrier sequence b) the above-stated polypeptides may be modified by arbitrary deletions of amino acids, by substitutions of one or more amino acids or by adding one or more amino

acids either at the N-terminus, the C-terminus or by insertion of one or more amino acids into the polypeptide sequence b), provided that the particle-forming capacity is maintained. Preferably, polypeptide sequence b) is myristylated.

If the carrier b) is a polypeptide sequence, both sequences a) and b) may be linked via one or more of the following interactions: hydrophobic anchoring (mediated by myristic acid), disulfide bridge formation, or both sequences may be connected by a peptide bond to form a fusion peptide. In the latter case optionally a spacer sequence may be inserted between polypeptide sequence(s) a) and polypeptide sequence b), which spacer sequence is linked to both polypeptides via peptide bonds.

The present invention furthermore provides a recombinant DNA molecule coding for a combination, that is useful for production of a medicament to treat chronic viral hepatic diseases. The recombinant DNA molecule comprises at least one first DNA sequence, optionally a second, a third and/or a fourth DNA sequence wherein

- i) said at least one first DNA sequence codes for at least one polypeptide sequence a) as defined above,
- ii) said second DNA sequence codes for a polypeptide sequence b) according to the above definition of the particle forming peptide,
- iii) said third DNA sequence codes for a spacer sequence, and
- iv) said fourth DNA sequence codes for a selection marker,

15

25

45

50

and wherein the DNA sequences are controlled by DNA elements essential for expression, and optionally have a common reading frame.

On account of the fact, that many amino acids are designated by more than one triplet, there exist several DNA sequences embraced by the present invention, which code for the above-defined peptide sequences a) and b). Apart from this, the invention further embraces recombinant DNA molecules, which differ from the above-defined recombinant DNA molecules by the fact, that up to 30% of the nucleotides may be substituted.

A further object of the present application is to provide a host cell transfected with a recombinant DNA molecule coding for the above combination, which is useful for treatment of chronically HBV-infected patients. This host cell may be a mammalian, a yeast or a bacterial cell. For the purpose of this invention it is preferred, that this cell does not produce any human serum proteins or any primate serum proteins other than the polypeptide(s) being comprised within the above combination.

The term "HBV S peptide" as used herein refers to the peptide encoded by the entire region of the HBV genome. The term "HBV pre-S2 peptide" as used herein refers to the peptide encoded by the entire pre-S2 and S regions of the HBV genome. The term "HBV pre-S1 peptide" as used herein refers to the polypeptide encoded by the entire pre-S1, pre-S2 and S regions of the HBV genome. The term "epitope" as used herein refers to a sequence of at least six consecutive amino acids encoded by the designated genome region (e.g. a "HBV pre-S2 epitope" refers to a sequence of at least six amino acids encoded by the pre-S2 region of the HBV genome). The term "T-cell epitope" as used herein refers to an epitope that interacts with receptors on the surface of T-cells to enhance or otherwise effect an immune response.

As used herein "antigenicity" means the ability to provoke an immune response (e.g. acting as an antigen), the ability to cause the production of antibodies (e.g. acting as an antigen) and/or the ability to interact with a cell surface receptor so as to enhance an immune response or production of antibodies.

The term "HBV" means any subtype of the virus, particularly adw, ayw, adr and ayr, described in the literature (P. Valenzuela, Nature Vol. 280, p. 815 (1979), Gerlich, EP-A-85 111 361, Neurath, EP-A-85 102 250). Examples of peptide sequences thereof, constituting polypeptide sequence(s) a), which mediate the antigenicity of one or more epitopes, are shown in the Sequence Listing (SEQ ID No. 17-20, 22).

Preferred embodiments of the present invention are the following combinations:

- HB S-antigen particles with specific epitopes (determinants) of the pre-S1-, pre-S2-, and/or core peptides;
- HB core-antigen particles with specific epitopes (determinants) of the pre-S1-, pre-S2-, S-peptide, and/or of the core antigens;
- Hepatitis A-antigen particles with specific epitopes (determinants) of the hepatitis B S-,pre-S1-, pre-S2-, and/or core-peptides.

Recombinant DNA molecules preferred for the present invention are characterized by the presence of sequences coding for polypeptide sequence(s) a), mediating the antigenicity of one or more T-cell epitopes, and for polypeptide b), which upon secretion forms particles having a diameter of 10nm or more, both of which are under control of a suitable promoter. As examples for sequences coding for a) there may be mentioned any of the sequences listed under ID numbers 1 to 24 in the sequence Listing. Examples for the DNA sequence coding for polypeptide sequence b) are represented by any of the ID-sequences 25 to 27 in the Sequence Listing.

Any of the 24 sequences (ID numbers 1 to 24) may be combined to any sequence disclosed under ID number 25 to 27 in the Sequence Listing, therein both orders a-b and b-a are included.

Hepatitis virus sequences used in the recombinant DNA construct of the present invention can be formed or isolated by any means including isolation and ligation of restriction fragments, chemical synthesis of oligonucleotides using a synthesizer (Cyclon, Bio-Search), and synthesis by the PCR method (T.J. White, N. Arnleim, H. E. Erlich, 1989; The Polymerase Chain Reaction, Technical Focus 5 (6)).

Preferred recombinant DNA molecules were formed by the ligation of synthetic oligonucleotides to a 5' Xbal-Bglll 3' fragment (ID number 27) from the S region of the HBV genome, which is derived from a Bglll-Bglll HBV fragment including the entire pre-S1-pre-S2-S-region, or to the entire S-region. Oligonucleotides used in making such constructs are summarized in Table I below.

Other preferred DNA molecules were formed by ligation of core sequences, which are prepared by the PCR method and which code for T-cell epitopes, to the core sequence of HBV (SEQ ID NO 25) functioning as polypeptide sequence b). Oligonucleotides used in preparing these constructs are given in Table II-1.

Table II-1

egpt = E coli xanthine quanine phosphoribosyl transferase

Preferred recombinant DNA molecules according to the present invention comprise, apart from the regions coding for polypeptides a) and b), an additional DNA sequence coding for a selection marker. Furthermore, they comprise all usual elements essential for the expression, such as promoter sequence, start codon and a polyadenylation signal.

Examples of suitable promoters are the methallothionein (MT), the U2 and the H2K promoter in case of using mammalian cells as a host cell. If yeast or bacterial cells are to be employed, appropriate yeast and bacterial promoters, such as the GCN4- and the GAL 1/10 promoter or the prokaryotic trp-and tac promoters, respectively, may be used.

In order to produce the combination of polypeptide(s) a) and polypeptide b) according to this application the recombinant DNA molecule is inserted into host cells by transfection (in case of mammalian cells), by transformation (in_case of yeast and bacterial cells), or by other means. As a host cells of any organism may be used that are capable of transcribing and translating recombinant DNA molecules, such as mammalian, bacterial and yeast cells.

Suitable mammalian cells according to this invention are for example VERO cells (a monkey kidney cell line), 3T3-, C127 and L cells (murine fibroblast cell lines), and CHO (Chinese hamster ovary) cells, which are either positive or negative in dehydrofolate reductase.

According to a specific embodiment of the present invention it is furthermore possible that the above-defined first DNA sequence and the above-defined second DNA sequence, which code for polypeptide sequence(s) a) and for a polypeptide sequence b), respectively, are present in different recombinant DNA molecules, in which case the host cells are cotransfected with both of these recombinant DNA molecules.

Table III gives an overview on how to combine suitable DNA sequences to get DNA constructs according to the present invention. It is to be noted that any constituents disclosed in this table may be combined to provide a DNA sequence which may be taken, if transfected into a host cell, to produce a combination (comprising polypeptides(s) a) and b)) as a medicament for the treatment of chronic viral hepatitis. The DNA sequences coding for the T-cell epitope sequences have been prepared synthetically (SYN) with a Biosearch Cyclon synthesizer, by PCR procedure (PCR), or by restriction enzyme fragmentation of the viral genome (GENE).

For the treatment of patients suffering from chronic viral hepatitis the combination of polypeptide

sequence(s) a) and a carrier b) may be formulated in any type of a pharmaceutical composition, which furthermore comprises a suitable diluent or pharmaceutical carrier material, such as a buffer solution.

The administration may be effected by any method, i.e. by parenteral (e.g. intravenous or intramuscular) or oral (e.g. by using typhoid bacterial cells to encapsulate the active substance) administration.

The pharmaceutical preparation comprises the above-described combination in sufficient concentration to elicit a response upon administration.

Brief Description of the Figures

10	Figure I	shows a DNA construct, coding for a promoter, a particle former sequence and a selection gene (described in Example 3/4).
	Figure II	shows a DNA-gene construct containing a promoter, an epitope with the entire HB-S-Ag and a selection gene (described in Example 3/18).
15	Figure III	shows a DNA construct presenting a promoter, a T-cell epitope with a particle former residue and a selection gene (described in Example 3/21).
75	Figure IV	shows the AST values of chimpanzee 1 during the Hepa-Care treatment (described in Example 10/1).
	Figure V	shows the antigen values of chimpanzee 1 during the Hepa-Care treatment (described in Example 10/1)
20	Figure VI	shows values of liver enzymes ALT and GGT of chimpanzee 1 booster treated three times with Hepa-Care (described in Example 10/2).
	Figure VII	shows values of liver enzymes ALT, AST, and GGT and of antigen of chimpanzee 2 during the Hepa-Care treatment (described in Example 10/3).
25	Figure VIII	shows the liver enzymes as determined for an untreated control chimpanzee (described in Example 10/3).
	Figures IX & X	show the antigen and antibody titers of patient 1 during the Hepa-Care treatment, respectively (described in Example 11).
	Figures XI &	show the antigen and antibody titers of patient 2 during the Hepa-Care treatment, respectively (described in Example 11).
30	Figures XIII &	show the antigen and antibody titers of patient 2 during the Hepa-Care treatment, respectively (described in Example 11). more specifically described by the following examples.

Example 1

35

5

1. Fractionated precipitation with polyethylene glycol (PEG)

The supernatant of HBV protein producing cultures was collected and split into portions of 2,400 ml. To each portion 144 g of PEG 6000 (Serva) were added and dissolved by stirring at room temperature for 20 minutes and was stirred for another 6 hours at 4°C. The precipitate was separated by centrifugation in 500 ml bottles in a GS 3 rotor at 9,000 rpm (15,000 x g) for 30 minutes at 10°C. The supernatant was collected and 144 g of PEG 6000 were added and dissolved as described above. The solution was stirred at 4°C for 3 hours. The precipitate from this solution was harvested as described above except that centrifugation was continued for 60 minutes.

2. Gel Chromatography

The material obtained after PEG precipitation was redissolved in 20 ml PBS and submitted to gel chromatography on A-5m (BioRad). Column dimensions were 25 x 1000 mm and 480 ml bed volume. In a typical fractionation run 1,000 µg of PEG precipitated HBV protein in 10 to 15 ml was loaded and eluted with PBS at a speed of 6 drops/min (18 ml/h). 3 ml fractions were collected. HBV protein eluted with the first peak. Collected fractions were submitted to a CsCl gradient.

3. Sedimentation in CsCl gradient

55

About 30 fractions covering the first peak in column chromatography on A-5m and containing prepurified HBV protein were collected to approximately 100 ml. This solution was adjusted to a density of 1.30 g'cc with CsCl and subsequently transferred to a polyallomer tube fitting into a SW 27.28 rotor

(Beckman). A gradient was bet by underlaying 4 ml of a CsCl solution of 1.35 g/cc and by overlaying 4 ml of 1.25 g/cc followed by 4 ml of 1.20 g/cc density. This gradient had been run at 28,000 rpm for 50 hours at 10° C. Thereafter the gradient was fractionated, and purified HBV protein floating in the 1.20 g/cc density layer was collected. The solution was desalted by three cycles of dialysis in bags against water.

Quantitative Determination of HBV protein

1. with Radioimmunoassay

In the AUSRIA II-125 "sandwich" radioimmunoassay (commercially available from Abbot), beads coated with guinea pig antibody to Hepatitis B surface antigen (Anti-HBs) were incubated with serum or plasma or purified protein and appropriate controls. Any HBsAg present was bound to the solid phase antibody. After aspiration of the unbound material and washing of the bead, human 125T-Anti-HBs was allowed to react with the antibody-antigen complex on the bead. The beads were then washed to remove unbound 125-Anti-HBs.

)-Anti-HBs HBsAq

)-Anti-HBs . HBsAg 125 I-Anti-HBs

)-Anti-HBs . HBsAq . 125 I-Anti-HBs

The radioactivity remaining on the beads was counted in a gamma scintillation counter.

2. with ELISA

In the Enzygnost HBsAg micro "sandwich" assay (commercially available from Behring), wells were coated with anti-HBs. Serum plasma or purified protein and appropriate controls were added to the wells and incubated. After washing, peroxidase-labelled antibodies to HBsAg were reacted with the remaining antigenic determinants. The unbound enzyme-linked antibodies are removed by washing and the enzyme activity on the solid phase was determined. The enzymatically catalyzed reaction of hydrogen peroxide and chromogen was stopped by adding diluted sulfuric acid. The colour intensity was proportional to the HBsAg concentration of the sample and was obtained by photometric comparison of the colour intensity of the unknown samples with the colour intensities of the accompanying negative and positive control sera.

Example 3

Preparation of gene constructs of the present invention containing promoter, desired antigen sequences and selection gene.

1. Isolation of the MT-promoter.

The plasmid pBPV-342-12 (ATCC 37224) was digested with the endonucleases BgIII and BamHI. Three DNA molecules were generated. The fragment of interest contains the methallothionein promoter and a pBR322 sequence comprising 4.5 kb and is easily detectable from the other fragments (2.0 kb and 7.6 kb).

The reaction was performed in a total volume of 200 μ I of reaction buffer at a final concentration of 0.5 μ g/ μ I DNA including 100 units of each restriction enzyme. The completion of the digestion was checked after incubation at 37° C for three hours by agarose gel electrophoresis at a 0.8% agarose gel. The reaction was stopped by adding 4 μ I 0.5 M EDTA.

The 4.5 kb fragment was separated from the other fragments by preparative 1.2% agarose gel electrophoresis. The DNA was eluted from the agarose gel on DE-81 Whatman filter paper from which the DNA was removed in a high salt buffer. The DNA was puritied by a phenol-chloroform extraction and two ethanol precipitations.

2. Ligation of a 1.8 kb fragment coding for the HBV-core-antigen.

A 1.8kb BamHI-BamHI fragment, containing the HBV-core coding regions was isolated from HBV-containing DNA. This fragment was ligated together with the 4.5 kb fragment containing the MT-promoter and the pBR residue (described in 1).

 $2~\mu I$ of the 1.8 kb fragment were mixed with $3~\mu I$ of the 4.5 kb fragment and ligated together in a total volume of 10 μI ligation buffer, containing 2 units T4-DNA ligase and 2 mM ATP at 14° C overnight.

The ligation mixture was added to 150 μ I competent bacterial cell suspension for DNA up-take. After the DNA up-take the bacterial cells were spread on LB agar plates containing 50 μ I/mI ampicillin at volumes of 50 to 300 μ I cell suspension per plate. The agar plates were incubated at 37 °C overnight. Single isolated bacterial colonies were screened for the presence of a plasmid containing the desired

fragments.

30

35

40

45

50

55

3. Screening for desired plasmid containing bacterial colonies.

Single colonies were picked with a toothpick and transferred to a LB-ampicillin medium containing tube (5 ml). The tubes were incubated overnight at 37° in a rapidly shaking environment. A mini-plasmid preparation of each grown bacterial suspension was made. The different resulting DNAs were proved by digestion with the restriction endonuclease BgIII. Two molecules were expected, a 400 bp fragment and a 5.9 kb fragment. The digestion was analysed by agarose gel electrophoresis. Plasmid DNA was isolated from the bacterial cells.

4. Insertion of a neomycin selection marker.

The plasmid resulting from (3) above was linearized by digestion with the restriction enzyme EcoRl. The reaction was performed in a total volume of 50 μ l and a final concentration of 1 μ g/ μ l plasmid DNA. 50 units of EcoRl were added and the digestion was proved after incubation at 37° C for three hours by agarose gel electrophoresis. The reaction was stopped by adding 1 μ l of 0.5 M EDTA and the DNA was precipitated with a final concentration of 0.3 M sodium acetate and 3-4 volumes of ethanol at -80° C for 30 minutes. The precipitated DNA was dissolved in 50 μ l distilled water.

2 µI of the linearized plasmid was mixed with 3 µI of the DNA fragment containing the methallothionein promoter and the neomycin selection gene (isolated from the plasmid pMT-neo-E (available from ATCC/Exogene) by digestion with the endonuclease EcoRI as a 3.9 kb fragment), and ligated together. Single bacterial colonies were screened for the presence of the desired plasmid.

5. Isolation of a fragment containing the U2 promoter sequence.

The plasmid pUC-8-42 (available from Exogene) was digested with the restriction endonucleases EcoRl and Apal. Two DNA molecules were generated. The fragment of interest contains the U2-promoter comprising 340 bp and is easily detectable from the other fragment (3160 bp). The digestion was performed in a total volume of 200 μ l reaction buffer at a final concentration of 0.5 μ g/ μ l DNA including 100 units of each restriction enzyme. The completion of the digest was checked after incubation at 37° C for three hours by agarose gel electrophoresis in a 0.7% agarose gel. The reaction was stopped by adding 4 μ l 0.5 M EDTA. The 340 bp fragment was separated from the plasmid DNA by preparative 1.2% agarose gel electrophoresis. The DNA was eluted from the agarose gel on DE-81 Whatman filter paper from which the DNA was removed in a high salt buffer. The DNA was purified by a phenol/chloroform extraction and two ethanol precipitations.

6. Insertion of the fragment containing the promoter sequence into a polylinker plasmid.

The plasmid pSP165 (commercially available from Promega Biotec) containing a polylinker sequence (containing the following restriction sites: EcoRI, SacI, Smal, Aval, BamHI, BgIII, SalI, PstI, HindIII) was linearized with the restriction enzyme EcoRI.

The reaction was performed in a total voume of 50 μ I and a final concentration of 1 μ g/ μ I plasmid DNA. 50 units of EcoRI was added and the digestion was proved after incubation at 37° C for three hours by agarose gel electrophoresis. The reaction was stopped by adding 1 μ I of 0.5 M EDTA and the DNA was precipitated with a final concentration of 0.3 M sodium acetate and 3-4 volumes of ethanol at -80° C for 30 minutes. The precipitated DNA was dissolved in 50 μ I distilled water.

2 μ I of plasmid DNA was mixed with 10 μ I of the fragment DNA containing the U2 promoter sequence, and ligated together in a total volume of 25 μ I of ligation buffer containing 2 units T4-DNA ligase and 2mM ATP at 14° C overnight. Thereafter, the DNA purified by phenol/chloroform extractions followed by two ethanol precipitations and dissolved in 10 μ I distilled water. The resulting sticky ends of EcoRI and ApaI had to be converted into blunt ends and ligated. The sticky ends were converted into blunt ends by reaction with the Mung bean nuclease as follows: to 25 μ I DNA (1 μ g/ μ I concentration) in reaction buffer 2G units of enzyme were added to give a final concentration of 1% glycerol and a final reaction volume of 35 μ I. After an incubation for 30 minutes at 30° C the DNA was purified by phenol-chloroform extractions followed by two ethanol precipitations. The DNA was dissolved again in 5 μ I of distilled water. The resulting blunt ends were ligated together in 15 μ I reaction volume containing 10 x more T4 ligase than used above and 2 mM ATP at 14° C overnight.

The ligation mixture was added to 150 µl competent bacterial cell suspension for DNA up-take. After the DNA up-take the bacterial cells were spread on LB agar plates containing 50 µg/ml ampicillin at volumes of 50 to 300 µl cell suspension per plate. The agar plates were incubated at 37° C overnight. Single isolated bacterial colonies were screened for the presence of a plasmid containing the desired U2-promoter fragment. The resulting plasmid was isolated from the bacterial cells and characterized by restriction enzyme analysis.

7. Ligation of synthetic oligo-DNA-nucleotide 89 (SEQ ID No.: 30) together with MT-promoter fragment (4.5 kb).

The 4.5 kb fragment (described in 1) containing the MT-promoter and a pBR residue were ligated together with the synthetic oligonucleotide 89 (SEQ ID No.:30). The ligation mixture was added to 150 µI competent bacterial cell suspension for DNA up-take. Single isolated bacterial colonies were screened for the presence of the desired plasmid. The new plasmid was proved by a digestion with the restriction endonucleases EcoRI and Xbal. Two molecules were expected, one 2.0 kb and one 2.6 kb.

8. Ligation of the synthetic oligonucleotide 101 (SEQ ID No.:32) together with plasmid (described in 7).

The plasmid (described in 7) was digested with BgIII and BamHI and a fragment of 13 nucleotides was removed (described in 1). The resulting fragment containing the first oligonucleotide 89 (SEQ ID No.:30), was ligated together with oligonucleotide 101 (SEQ ID No.:32), a BgIII-BamHI fragment. After DNA up-take single cells were screened for the presence of the desired plasmid. The new plasmid was proved by a digestion with the endonucleases EcoRI and XbaI, or EcoRI and BgIII.

9. Ligation of synthetic DNA-oligonucleotide 99 (SEQ ID No.:31) to the 4.5 kb fragment (described in 1).

The 4.5 kb fragment (BgIII-BamHI) was ligated together with the DNA oligonucleotide 99 (SEQ ID No.: 31). After screening of single bacterial colonies, containing different DNAs, the desired plasmid was characterized by digestion with EcoRI, resulting in two fragments, 1.9 kb and 2.7 kb, and by positive linearization with BgIII or BamHI.

The new plasmid was then digested with Pstl and BamHl. Two molecules were expected, one 2.6 kb fragment, containing a pBR residue, the MT-promoter and the oligonucleotide and a 2.0 kb pBR residue. The 2.6 kb fragment was isolated.

10. Ligation of the 2.6 kb fragment of the plasmid described in 9, with a fragment isolated from plasmid (described in 8).

The plasmid (described in 8) containing the DNA oligonucleotides 89 and 101 (SEQ ID No.:30 and 32, respectively) was digested with Pstl and Bglll. Two fragments were expected. A 2.5kb fragment containing a pBR residue and the MT-promoter and 2.2 kb fragment, containing a pBR residue and both oligos.

This 2.2 kb fragment was ligated together with the 2.6 kb fragment, containing the pBR residue, the MT-promoter and oligo 99 (SEQ ID No.:31) described in 8.

After screening for the desired plasmid, it was characterized by restriction endonuclease digestion with BgIII-XbaI. Two fragments were expected, a 270 bp fragment of the oligo-DNA-nucleotides and a 4.5 kb fragment of the MT-promoter and the pBR.

11. Ligation of the 2.3 kb HBV BgIII-BgIII fragment.

5

10

15

20

25

30

35

45

50

55

A 2.3 kb Bglll-Bglll fragment containing the HBV pre-S1, pre-S2 and S coding regions was isolated from HBV-containing DNA. The 2.3 kb fragment was ligated together with the 4.5 kb fragment (obtained as described in 1) containing the methallothionein promoter.

2 μl of the 2.3 kb fragment was mixed with 3 μl of the 4.5 kb fragment and ligated together in a total volume of 10 μl ligation buffer, containing 2 units T4-DNA ligase and 2 mM ATP at 14° C overnight.

The ligation mixture was added to 150 μ l competent bacterial cell suspension for DNA up-take. After the DNA up-take the bacterial cells were spread on LB agar plate containing 50 μ g/ml ampicillin at volumes of 50 to 300 μ l cell suspension per plate. The agar plates were incubated at 37° C overnight. Single isolated bacterial colonies were screened for the presence of a plasmid containing the desired fragment.

12. Conversion of a part of the HBV-gene sequence with HBV -core epitopes.

The plasmid resulting from 11 above was digested with the endonucleases BgIII and Xbal. Two molecules were expected, one 550 bp fragment and a 6.25 kb fragment which was isolated after agarose gel electrophoresis.

The 6.25 kb fragment was ligated together with the 270 bp fragment (after digestion with BgIII and XbaI and fragment isolation as described above) of the plasmid described in 10, coding for an epitope part of the HBV-core gene.

The ligation mixture was added to 150 µl competent bacterial cell suspension for DNA up-take. Single isolated bacterial colonies were screened for the presence of the desired plasmid. The new plasmid was proved by a digestion with BamHI. Three molecules were expected, a 950 bp, a 450 bp and a 5,150 bp fragment.

13. Preparation of a "vehicle" plasmid.

The plasmid (described in 11) was digested with EcoRI and Xbal. Two molecules were expected, one 2,450 bp fragment and a 4,350 bp fragment which was isolated after gel electrophoresis.

This 4,350 bp fragment was ligated together with the oligo-DNA-nucleotide 39 (SEQ ID No:29) coding for the entire DNA-sequence of HBV-S-gene from ATG to the Xbal site, wherein the ATG was changed into ATA.

14. Core-epitope upstream of the entire HBV-S gene.

This "vehicle" plasmid was then digested with Pstl and Xbal, two molecules were expected, one 600 bp plasmid residue and a 3,850 bp fragment which was isolated and ligated together with a Pstl-Xbal fragment of 2,800 bp (2,700 bp) isolated after digestion of the plasmid described in 10.

After screening for the desired plasmid, it was characterized by restriction endonuclease digestion with EcoRI and Xbal, EcoRI and Bglll and BamHl.

15. Insertion of a selection marker.

5

10

15

20

25

30

35

40

45

50

55

The plasmid (described in 14) was linearized with Eco RI. The reaction was performed in a total volume of 50 μ l and a final concentration of 1 μ g/ μ l plasmid DNA. 50 units of EcoRI were added and the digestion was proved after incubation at 37° C for three hours by agarose gel electrophoresis.

The reaction was stopped by adding 1 µl of 0.5 M EDTA and DNA was precipitated with a final concentration of 0.3 M sodium acetate and 3-4 volumes of ethanol at -80° C for 30 minutes. The precipitated DNA was dissolved in 50 µl distilled water.

2 μl of the linearized plasmid was mixed with 3 μl of the DNA fragment containing the methallothionein promoter and the neomycin selection gene (described in 4) and ligated together. Single bacterial colonies were screened for the desired plasmid which was isolated, purified and characterized.

Each gene construct described above can be constructed also with the U2-promoter whereby the MT-promoter-containing DNA fragment, after digestion with EcoRI and Bglll, is replaced by a DNA fragment containing the U2-promoter isolated after digestion with EcoRI and BgIII.

16. Isolation of the E coli xanthine quanine phosphoribosyl transferase (egpt) selection gene.

The fragment containing the egpt selection gene was isolated after digestion of the plasmid pMSG with BamHI and BgIII (1.8kb) and ligated together with a 4.5 kb fragment (BgIII-BamHI, described in 1) containing the MT-promoter. After screening for the desired plasmid it was isolated, purified and finalized by a conversion of the BamHI site into an EcoRI site.

17. Isolation of desired DNA sequences by PCR-method.

One DNA fragment (400 bp) was isolated after gel electrophoresis. It was generated by PCR-method (described in Example 5) by using the specific oligonucleotides 131 and 132 (SEQ ID No.:33 and 34) as primers.

The DNA fragemnt was digested with the endonucleases BamHI and XbaI and then purified by gel® electrophoresis. The isolated PCR-fragment was ligated together with a 6.25 kb fragment which was isolated from the plasmid (described in 13) after digestion with BgIII and Xbal. After DNA up-take and bacterial transformation the single bacterial colonies were screened for the desired plasmid.

18. Insertion of a selection marker.

The plasmid (described in 17) was finalized by adding a selection gene to the plasmid (described in 15).

19. Isolation of the H2K promoter.

The H2K-promoter was isolated as an EcoRI and BgIII fragment (2kb) from pSP65H2 (available from

In all constructs described all promoters are replaceable as EcoRI/BgIII fragments.

20. Conversion of a part of the HBV-gene sequence.

The plasmid resulting from 11) above was digested with the endonucleases BgIII and Xbal. Two molecules were expected, one of which is a 6.250 kb fragment which was isolated after agarose gel electrophoresis.

The 6.250 kb fragment was ligated together with oligo-DNA-nucleotide 23 (SEQ ID No.:28). The ligation mixture was added to 150 µl competent bacterial cell suspension for DNA up-take. Single isolated bacterial colonies were screened for the presence of the desired plasmid. The new plasmid was proven by a digestion with the endonucleases EcoRI and BgIII. Two molecules were expected, one 1,9 kb and one 4.450 kb.

21. Insertion of a egpt selection marker.

The plasmid (described in 20) was linearized with EcoRI. The reaction was performed in a total volume of 100 μl and a final concentration of 0.6 μg/μl plasmid DNA. 60 units of EcoRI were added and the digestion was proved after incubation at 37° C for three hours by agarose gel electrophoresis. The reaction was stopped by adding 2 μl of 0.5 M EDTA and the DNA was precipitated with a final concentration of 0.3 M sodium acetate and 4 volumes of ethanol at -80° C for 1 hour. The precipitated DNA was dissolved in 50 µl distilled water.

2 µl of the linearized plasmid was mixed with 3 µl of the DNA-fragment (3.7 kb) containing the methallothionein promoter and the egpt selection gene (described in 16) by digestion with EcoRI and ligated together. Single colonies were screened for the presence of the desired plasmid. Each of the

described gene constructs in Table III are preparable in the same way as described above.

Example 4

Transfection of Mammalian Cells with Constructs of the Present Invention.

In order to achieve secretion of substantial amounts of the HBV peptides encoded by constructs of the present invention, mammalian cells must be transfected with a DNA construct of the present invention. The cotransfection was performed in two steps (i.e. a separate transfection for each construct) or in a single step (i.e. one transfection using preparation of both constructs). Cotransfection was confirmed either by use of different selection markers on the two constructs or by detection of secretion of expression products of both constructs by immunoassay.

Alternatively, a sequence encoding the HBV peptide sequence of the present invention and a separate sequence encoding the entire S or core or HAV protein could be combined in a single construct.

Example 5

15

20

Polymerase chain reaction (PCR).

The polymerase chain reaction allows to amplify specific DNA necleotide sequences of a selected region of a known genomic sequence in vitro by more than a millionfold (Thomas J. White, Norman Arnleim, Henry A. Erlich 1989: The polymerase chain reaction. Technical Focus, Vol. 5. No. 6; S. Kwok and R. Higuchi 1989: Avoiding false positives with PCR. Nature, Vol. 339, pp 237-238).

DNA isolated from cells or plasmid DNA is treated to separate its complementary strands. These strands are then annealed with an excess of two DNA oligonucleotides (each 20 - 25 base pairs long) that have been chemically synthesized to match sequences separated by X nucleotides (where X is generally between 50 to 2,000 base pairs).

The two oligonucleotides serve as specific primers for in vitro DNA synthesis catalysed by DNA polymerase which copies the DNA between the sequences corresponding to the two oligonucleotides. If the two primer oligonucleotides contain the correct sequence it is possible to create new digestion sites at the 5' and 3'.

After multiple cycles of reaction, a large amount of a DNA fragment of the desired length was obtained, purified by gel electrophoresis and characterized by restriction enzyme digestion and agarose gel electrophoresis. The amplified, purified DNA fragment was then used to ligate it together with other fragments i.e. plasmid.

The PCR-DNA fragments were amplified with blunt end. To get sticky end (for the ligation procedure) the fragment has to be digested with the desired endonucleases and purified again.

The PCR-reaction will work for 20 to 30 cycles. One cycle is separated into three steps with different reaction times and different reaction temperatures which is controlled by a PCR-thermo-cycler. The first step is "Denaturation" of the matrix-DNA (1 min-95° C), the second step is "Hybridisation" of matrix DNA and primers (1 min/55° C) followed by "Polymerisation" (2 min/72° C).

The final volume for one assay is 30 μ l for example, which contains the following final concentrations: PCR-buffer (1 x), nucleotide-mix with 200 μ M of each of the four nucleotides, 200ng for 30 μ l of each of the two primers, 0.5 units Taq-Polymerase per 30 μ l aqua bidest.

Example 6

45

50

Culturing of Transfected Cells to Secrete Protein

The recipient cells (C127 or CHO-cells available from ATCC) were seeded in normal growth medium (DMEM + 10% Fetal Calf Serum, Glucose and Glutamine) into petri-dishes (1-2 x 10^6 cells per dish, ϕ 10 cm) at day 1. The next day the medium was removed (4 hours before the DNA precipitate was added onto the cells), and the cells were washed twice with 1 x PBS. Then 8 ml DMEM without FCS were added, 4 hours later the DNA precipitate (prepared as described below) was added to the cells. Again after 4 hours the medium was removed, 3 ml of Glycerol-Mix (50 ml 2 x TBS buffer, 30 ml glycerol, 120 ml distilled water) were added. The Glycerol-Mix was immediately removed after an incubation at 37° C for 3 minutes and the cells were washed with 1 x PBS. The cells were cultivated overnight with 8 ml of DMEM with 10% FCS.

After 48 hours, the cells were recovered from the dish by treating with Trypsin-EDTA-Solution (0.025% Trypsin + 1mM EDTA). Afterwards, to remove the Trypsin-EDTA the cells were washed with 1 x PBS, suspended in DMEM with 10% FCS and distributed into 24 costar-well-plates (cells from one dish into four 24-well-plates).

When the cells had grown well, selection medium was added (concentration 0.5 - 1 mg/ml of neomycin or: xanthine (250 µg/ml), hypoxanthine (15 µg/ml) or adenine (25 µg/ml), thymidine (10 µg/ml), aminopterine (2 µg/ml), mycophenolic acid (25 µg/ml) for eco-gpt, for example). The medium was changed every week. The first growing cell colonies were seen after 2 weeks.

To 10 μg of plasmid DNA and 20 μg of carrier-DNA (salmon sperm DNA, calf-thymus DNA) TE-buffer (10 mM Tris-HCl, 1 mM EDTA, pH 7.05) was added to a final volume of 440 μ l and mixed together with 60 μ l 2 M CaCl₂. Then the same amount of 2x TBS (Hepes 50 mM, NaCl 280 mM, Na₂HPO₄ 1.5 mM, pH 7.05) was added and mixed well. The precipitation solution was incubated for 30 minutes at 37° C and added directly to the cells which were to be transfected.

Example 7

Preparation of the Adjuvant of Purified Particles.

To the desired concentration of antigen suspended in sterile saline, 1:10,000 volume Thimerosol, 1/10 volume of filter-sterilized 0.2 M KAl(SO₄)₂•12 H₂O were added. The pH was adjusted to 5.0 with sterile 1 N NaOH and the suspension was stirred at room temperature for 3 hours. The alum-precipitated antigen was recovered by centrifugation for 10 minutes at 2,000 rpm, resuspended in sterile normal saline containing 1:10,000 Thimerosol and aliquoted under sterile conditions.

Example 8

Purification of Hepatitis-B-core Antigen.

The cell supernatant of HB-core-antigen-secreting cells was collected and concentrated by ultrafiltration. The concentrate was cleared by centrifugation at 20,000 rpm for 15 minutes at 4° C in a Beckman SW28 rotor.

Particle formaiton was tested by sucrose density centrifugation (0-45% sucrose) in a Beckman SW28 rotor for 24 hours at 28,000 rpm and 4° C. The gradient was fractionated and the single fractions were analyzed by Elisa.

Example 9

Studies of administering Hepa-Care in Chimpanzees:

Hepa-Care are particles presenting hepatitis B surface antigens (S1 and S) in a specific formulation (ratio 50:50), which are used for the treatment of chronic carriers of hepatitis virus.

Experiment 1

A Hepatitis-B-carrier chimpanzee 1 was treated (intramuscularly) with Hepa-Care at time 0, 4, and 8 weeks with a dosage of 18 μg per injection.

The liver enzymes were monitored (Fig. IV) as well as the hepatitis-B antigen level (Fig. V).

Experiment 2

Chimpanzee 1 after treatment described above was given a booster treatment at week 30, 34, and 38. The results are shown in Fig. VI.

Experiment 3

5

10

Chimpanzee 2 was treated with Hepa-Care, but contrary to chimpanzee 1 it was given intravenously. The dosage was 2 mg. The results are shown in Fig. VII.

From a control chimpanzee 3 the liver enzymes were also monitored and shown in Fig. VIII.

       HBsAq
                   pos.
       anti-HBs
                   neg.
       HBeAg
                   neg.
       anti-HBe
                   pos.
20
       anti-HBc
                   neg.
    was treated (i.m.) with Hepa-Care at month 0, 1, 6, and 7. The results of the antigen and antibody
    measurements are given in Fig. IX and X.
    Patient 2 (female, age = 48 years, disease for 12 years):
  Hepatitis-B parameters:
       HBsAg
                   pos.
       HBeAg
                  . neg.
       anti-HBs
                   neg.
       anti-HBe
                   pos.
       anti-HBc
                    pos.
30
    was treated (i.m.) with Hepa-Care at month 0, 1, and 6. Results of antigen and antibody measurements are
    shown in Fig. XI and XII.
    Patient 3 (female, age = 41 years, disease for 5 years):
    Hepatitis-B parameters:
       HBsAg
                    pos.
35
       HBeAg
                    neg.
       anti-HBs
                    rreg.
       anti-HBe
                    pos.
    was treated at month 0, 1, 2, and 5 with Hepa-Care (i.m.). The measured values of HBs antigen and anti-
    HBs antibodies are shown in Fig. XIII and XIV.

shows a DNA construct presenting a promoter, a T-cell epitope with a particle former residue and a selection gene (described in Example 3/21)

shows a DNA-gene construct containing a promoter, an epitope with the entire HB-S-Ag and a selection gene (described in Example 3/18)

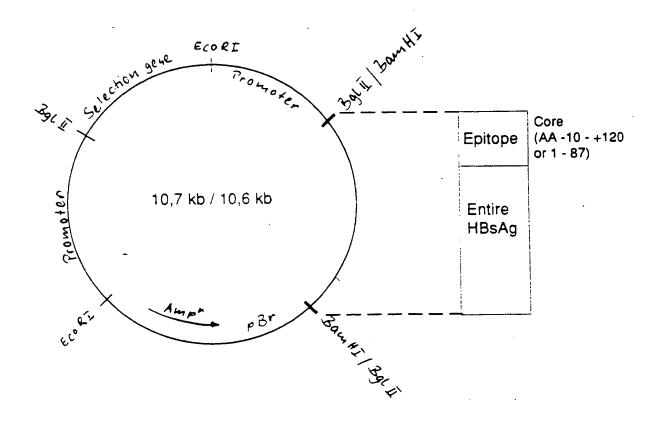

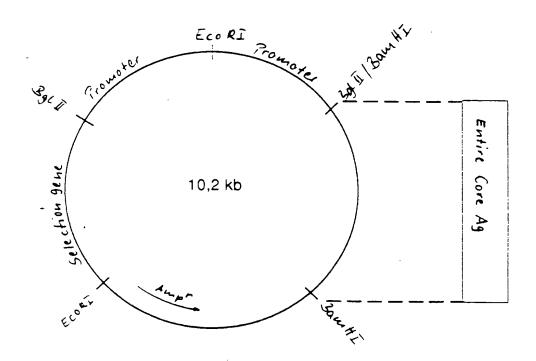

Fig. I shows a DNA construct, coding for a promoter, a particle former sequence and a selection gene (described in Example 3/4)

- 16. Use of a combination according to any of the claims 1 to 15 for the production of a medicament for the treatment of chronic viral hepatitis.
- 17. A recombinant DNA molecule coding for a combination according to any of the claims 1 to 16 comprising at least one first DNA sequence, optionally a second, a third and/or a fourth DNA sequence,
 - i) said at least one first DNA sequence codes for at least one polypeptide sequence a) according to one of claims 1 to 6.
 - ii) said second DNA sequence codes for a polypeptide sequence b) according to one of claims 8 to 12,
 - iii) said third DNA sequence codes for a spacer sequence according to claim 15, and
 - iv) said fourth DNA sequence codes for a selection marker,
 - and wherein the DNA sequences are controlled by DNA elements essential for expression, and optionally have a common reading frame.
- 18. A recombinant DNA molecule according to claim 17, characterised in that in the first DNA sequence(s) up to 30% nucleotides may be substituted.
- 19. A host cell transfected with a recombinant DNA molecule according to either of claims 17 or 18.
- 20. A host cell according to claim 19, characterised in that said host cell is selected from the group comprising mammalian, yeast and bacterial cells.

40

- a) can be bound to carrier b) by adsorption, any chemical bonding or secondary valences.
- 2. A combination according to claim 1, characterised in that polypeptide sequence(s) a) mediate(s) the antigenicity of a T cell-activating epitope in direct or indirect way.
- 3. A combination according to claim 1 or 2, characterised in that said polypeptide sequence(s) a) is a polypeptide of hepatitis B virus.
- 4. A combination according to one of claims 1 to 3, characterised in that polypeptide sequence(s) a) is the amino acid sequence of one or more members selected from the group comprising the HB viral peptides pre S1, pre S2, S and the core antigens.
 - 5. A combination according to one of claims 1 to 4, characterised in that the polypeptide sequence(s) a) may be modified:
 - i) by having arbitrary deletions, whereby an epitope comprising at least six consecutive amino acid residues is preserved,
 - ii) by having substitutions of one or several amino acids, or

15

20

35

- iii) by carrying an additional amino acid sequence either at its N-terminus, at its C-terminus or as an insertion into the polypeptide sequence(s) a).
- 6. A combination according to one of claims 1 to 5, characterised in that polypeptide sequence(s) a) is myristylated.
- 7. A combination according to one of claims 1 to 6, characterised in that the carrier b) is a polysaccharide, a hydrophobic polymer or an inorganic molecule having particle form.
 - 8. A combination according to one of claims 1 to 6, characterised in that the carrier b) is a second polypeptide sequence.
- 30 **9.** A combination according to claim 8, characterised in that polypeptide sequence b) upon secretion forms particles having a diameter of at least 10nm.
 - 10. A combination according to claim 8 or 9, characterised in that polypeptide sequence b) is a substantial part of or the complete amino acid sequence of a polypeptide selected from a group comprising the HBV S-peptide, the HBV core-, the HAV core- and the HIV core-antigen as well as the surface antigens of poliovirus, HAV or HIV.
 - 11. A combination according to one of claims 8 to 10, characterised in that polypeptide sequence b) may be modified
 - i) by having arbitary deletions, whereby the particle forming capacity is preserved,
 - ii) by having substitutions of one or several amino acids, or
 - iii) by carrying an additional amino acid sequence either at its N-terminus, at its C-terminus or as an insertion into the polypeptide sequence b).
- 12. A combination according to one of claims 8 to 11, characterised in that polypeptide sequence b) is myristylated.
 - 13. A combination according to one of claims 1 to 6 or 8 to 12, characterised in that the polypeptide sequences a) and b) are linked via disulfide bridges.
 - 14. A combination according to one of claims 1 to 6 or 8 to 13, characterised in that the polypeptide sequences a) and b) are linked via "hydrophobic anchoring" (mediated by myristic acid).
- 15. A combination according to one of claims 1 to 6 and 8 to 14, characterised in that the polypeptide sequences a) and b) are linked by a peptide bond, wherein optionally a spacer sequence is inserted in between polypeptide sequence(s) a) and polypeptide sequence b), said spacer sequence being linked via peptide bonds to polypeptide sequences a) and b).
